

ABSTRACT

A wireless communication unit comprises circuitry configured to receive a voice data block associated with a first logical channel. The circuitry further configured to receive a non-voice data block associated with a second logical channel. The voice data block and non-voice data block carried by a wireless channel set during a time period. The wireless channel set comprises at one wireless channel or a plurality of wireless channels. The wireless channel is associated with a subscriber unit. Circuitry is configured to insert information into a non-voice block, when the non-voice data block is missing in the wireless channel set during the time period.
